DATA ANALYTICS INDEX

We asked 10 AI agents about the same business. They disagreed.

By Aritra Ghosh · 2026-10-21 · 9 min read · 1882 words

> **Disclosure:** We commissioned this benchmark at Supaboard, and we're a participant. Claude designed and ran it for us; its Opus and Sonnet models are participants too. These are vendor-reported results from our own repository. We have not published an independent grading audit. (Benchmark notes)

The paying customers your CRM cannot see

Which customers are paying us but missing from the CRM?

That's a useful question for an operations team. Someone needs to find those accounts, work out how much revenue they represent, and decide what to fix. An answer that looks plausible can still send the team after the wrong customers.

In the Data Analytics Index, the answer key identified 214 customers representing $59,658.33 in monthly recurring revenue. Claude Opus 5.5 and Supaboard (Stella Pro) matched that result and received full credit. Hex reported 191 customers, Basedash 263, and ChatGPT 305, each with a different revenue total. (CRM-gap results)

> **What stood out**
>
> - Our original table reports a tie, but two targeted Supaboard adjustments reduce its score to 33; a uniform regrade remains unfinished.

- Customer matching and revenue by industry separated the agents more than several revenue calculations did.
- We found 136 recorded attempts and have documented one selection rule for the regrade.

A database with enough mess to disagree about

We selected tools we could access with our available resources. We could not obtain access to Omni, Snowflake CoWork or Databricks Genie without a sales-led process, so they are absent from this edition. We therefore have no results for those products.

The test business, Corvia Systems, is fictional. It sells scheduling and dispatch software by the seat to clinics and field-service companies. Its Postgres database contains roughly twenty tables across billing, CRM, product usage, support, a legacy billing export and reference data. (Benchmark setup)

Records are duplicated or inconsistent. Systems do not share clean keys. The agents received no documentation, hints or semantic layer to settle the definitions for them.

Each task began in a fresh chat with the same short company introduction. The thirteen questions covered familiar work: recurring revenue, retention, overdue invoices, sales performance, usage and support. Some recorded exchanges include a clarification telling the agent to use its judgment and state its assumptions. (Question protocol, Supaboard answers)

This setup tests investigation of unfamiliar data. An evaluation with approved definitions or a curated semantic model would test a different workflow.

The reported results

Supaboard (Stella Pro) and Claude Opus 5.5 each earned 35 of 39 available points. (Published ranking) The table reproduces the report reviewed on 21 October 2026, with "accuracy" labeled as the share of available points. These are the original vendor-reported scores. We are not treating the shared-first result as settled; our adjustment and attempt audit follow the table.

Agent	Points / 39	Share of available points
Claude Opus 5.5	35	89.7%
Supaboard (Stella Pro)	35	89.7%
Claude Sonnet 5.5	31	79.5%
Lightdash	28	71.8%
Basedash	27	69.2%
ChatGPT (GPT-6)	26	66.7%

Agent	Points / 39	Share of available points
Dot	22	56.4%
Hex	19	48.7%
Sigma	17	43.6%
Metabase	0	0.0%

Metabase's zero reflects the rule requiring the agent to execute its queries: on many tasks, it returned SQL without running it. The transcript separately records results after Claude clicked Run; those evaluator-run results were excluded from Metabase's score. (Metabase results)

Each response earns up to three points, including partial credit. Divide total points by 39 and multiply by 100 for the normalized percentage; the Data Analytics Index adds ten, so its maximum is 110. The reported joint leaders have an index of 99.7. (Scoring formula)

What changes at 33 points

Two changes alone take Supaboard from 35 to 33 points, or 84.6% of available points and an index of 94.6. That is below Opus's published 35 and above the other published totals. This calculation holds every other grade fixed. A replacement leaderboard requires a review of all selected attempts. (Published totals and formula)

Supaboard question	Published grade	Targeted adjustment	Reason
Q4: recognized revenue	3	2	Treat $2.6M as a reported number, without a coarse-rounding bonus
Q6: receivables	3	2	The final recommended debtor list includes uncollectible balances
Total, all other grades held fixed	35	33	A limited adjustment, not a full regrade

For Q4, $2.6M is about 1.2% above the $2,568,266.89 key. Our original precision clause allowed full credit, and even used this answer as its example. Hex's $2,601,203.52, about 1.3% above the same key, earned two points. Removing the coarse-rounding exception is a change to our rubric, and we need to apply it to every agent. (Revenue results)

For Q6, Supaboard's first conversation ends with a $649.1K headline and a debtor list containing uncollectible balances, while retaining the exact $305,557.25 open-invoice alternative. Basedash received two points for the same pattern. A final-answer completeness rule would give both two points. Supaboard's earlier response had the open-only list, so the rule must explicitly prevent a superseded answer from supplying the missing credit. (Supaboard Q6, Basedash Q6)

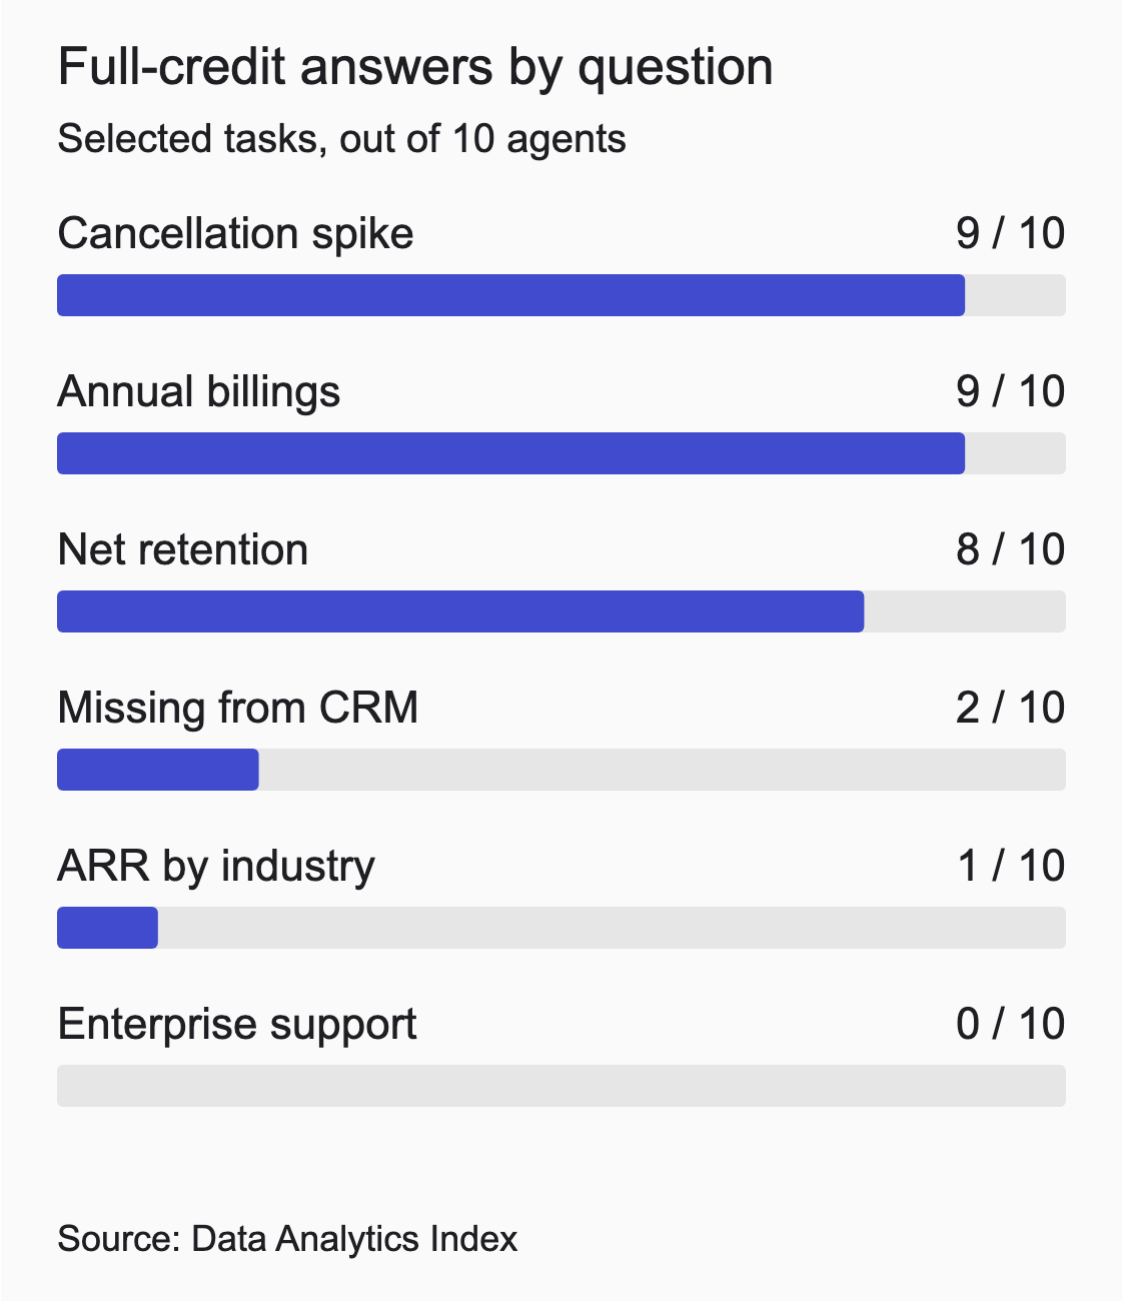

Opus's support answer includes a replied-only median of about 101 minutes that appears eligible for two points under the alternative-answer rule, versus its published one. Sonnet's and Lightdash's customer-count alternatives also fall inside the stated five-percent band. A consistent review could therefore change Opus to 36, Sonnet to 32 and Lightdash to 29, all else fixed. We still need to grade Supaboard's first recorded appointments answer. We will publish a replacement leaderboard only after the same rules have been applied across the selected attempts. (Opus Q12, customer-count results)

Revenue by industry was harder than the cancellation spike

Nine agents received full credit for identifying the May cancellation spike as a Meridian Health consolidation involving sixteen clinics on 15 May; nine also received full credit for comparing annual billings. (Question results)

The picture changed when the question was annual recurring revenue (ARR) by industry. The key put healthcare at 31.0%. Only Opus received full credit; the reported healthcare shares ranged from Basedash's 14.15% to Sonnet's 47.2%. (ARR results)

All the agents that returned a figure in that table named healthcare. A reader checking only the industry label would miss the disagreement over its share of revenue.

Selected tasks, vendor-reported. Full credit follows the benchmark's rounding and alternative-answer rules. (Published full-credit counts)

The practical question is whether the result uses the customer population and revenue definition you intended. A percentage on its own cannot tell you that. You need the underlying records and the agent's assumptions to check it.

Where Supaboard fell short

Supaboard's original total includes misses. It returned a healthcare share of 29.16% against the 31.0% key and received one point for a reasonable alternative method. (Supaboard ARR result)

Its published scores also include two points each for the appointments trend and enterprise support questions. (Supaboard scores)

For seat utilization, Supaboard's headline was "0.57". Its full-credit figure, about 57.52%, comes from the uncapped active-customer row dated 15 September in a sensitivity table. Opus's 57.4% headline earned two points. Our original rubric allowed matching alternatives, so that credit is retained in the limited 33-point

adjustment; it does not show that Supaboard's month-end headline was more accurate. A regrade that requires a particular snapshot must check the full prompt before accepting the mid-month row. (Supaboard Q10, seat-utilization results)

Speed needs a careful comparison

Basedash had the fastest reported average at 68 seconds. Opus averaged 149 seconds and Supaboard 192 seconds. (Response times)

These averages belong to the original mixed-attempt selection. Some recorded timers come from reruns, including Supaboard Q6 and Sigma Q7. We need timings tied to the selected conversations before publishing revised speed comparisons. (Supaboard Q6, Sigma Q7)

Original scoring and limits

The original rubric accepts the key figure as a headline, alternative or sensitivity-table result. Counts must match for full credit; money and rates can fall within 0.1% or match at the written precision. Close answers within five percent earn two points. (Scoring rules)

This is one synthetic SaaS database. Full prompts, the answer key and the database are available to reviewers on request. Claude and ChatGPT used Neon project-owner access; the other agents used a shared read-only role. We report no database writes; we have not measured repeated-run variability. (Protocol and access notes)

One attempt-selection rule for every agent

For the regrade, we select the first completed recorded conversation for each question. Standardized clarification turns stay within that attempt. The final response and its supporting tables determine the score; an explicitly superseded earlier recommendation cannot rescue the final answer. A completed interaction that returns unexecuted SQL still counts as an attempt. Later attempts stay visible but cannot replace the selected one because they score better.

The published records contain 136 attempts across 130 agent-question pairs: six pairs have two attempts. These counts describe the published record, not a complete platform event log. (Full answer records)

Agent	Recorded attempts	Questions with a second attempt
Claude Opus 5.5	13	None recorded
Supaboard (Stella Pro)	16	Q6, Q11, Q13
Claude Sonnet 5.5	13	None recorded
Lightdash	14	Q10
Basedash	13	None recorded

Agent	Recorded attempts	Questions with a second attempt
ChatGPT (GPT-6)	13	None recorded
Dot	14	Q1
Hex	13	None recorded
Sigma	14	Q7
Metabase	13	None recorded

Supaboard has second attempts on Q6, Q11 and Q13. Under this rule, its first conversations are selected in all three cases, including Q13's 863-customer answer. Dot Q1, Lightdash Q10 and Sigma Q7 also select their first conversations. (Supaboard records, Dot records, Lightdash records, Sigma records)

We cannot carry Supaboard's Q11 grade across automatically. Its first conversation states 80,467 human appointments and separately 10,459 Zapier appointments for September; the credited 142,668 total is explicit in the rerun. The first conversation references a chart whose full payload is absent from the README. We need that payload or a database check before assigning its replacement grade. We must also match timings to the selected attempts before publishing revised speed averages. (Supaboard Q11)

The work after the answer

The benchmark measures answers to business questions. It did not score building dashboards, preparing a weekly deck or sending the recurring report. Similar answer scores leave those parts of the product decision open.

Supaboard is the one AI agent that does the whole analyst job on your own database. After an answer, the same agent can build a dashboard, prepare a report or deck, and run the recurring analysis on a schedule. (Dashboards, Automations)

Give it seven days with one weekly review you already run. Bring twenty questions whose answers you know, teach the agent your definitions, and score its answers with evaluations. Then check whether it can produce and deliver the review you need. That tests both the answers and the work that follows them.

Start Free, or book a 30-minute demo to scope that evaluation. Seven days is the suggested evaluation window; access and AI allowances follow the current plan.
